1 Requirement Analysis

1.1 Introduction

1.1.1 Purpose

The purpose of this application is to introduce a dating system different to any others: a date rental service. Instead of putting time and effort in looking for a date, in which some cases people are not willing or feel unable to put in, we want to offer them the possibility of renting a suitable dating partner with certain desired characteristics. Consider for instance, an event in which going alone would be rather awkward; rent a date of your liking instead! Sometimes people feel lonely and would simply like some companies to do their preferred activities: walking around a park, going to a restaurant or a cinema, talk at a café, etc. We propose an interactive platform in which people can do this easily.

1.1.2 Scope and special requirements

We limit ourselves to the region of Greater Montreal. Due to safety and legal purposes, we limit the kind of activities allowed on our platform to typical activities in public places, by common transportation and within the applicable area. We also limited ourselves to the general browsing and booking system rather than the security and supervision system, which required some external resources.

1.1.3 Terminology

-

1.2 Database Description

1.2.1 Entities and attributes

Our database is constituted of the following entities with their respective attributes:

1. **Person:** A person is any individual involved with the service. It is-a Manager, is-a Product or is-a Customer. It contains basic attributes such as first and last name, date of birth and email, sex (male/female), city of residence, a phone number, city of residence (Montreal, Longueuil, Laval, etc.), a unique username which is its primary key and a password.
2. **Manager:** A manager is a sub-entity of the Person entity and serves as an administrator of our platform. It does not contain any additional attribute other than the one inherited from Person.
3. **Mate:** A Mate is a sub-entity of the Person entity, who is the dating partner that customers can choose to go on a date with. It comprises additional attributes which include a nickname, a general description, the Mate's height, weight, description, languages he/she speaks, preferences in terms of dating activities, and an hourly rate which is the price customers pay to rent the Mate for a date.
4. **Application:** In order for a Product to make part of the dating service system, it needs to submit an application. Application is a weak entity which depends on a Product entity. The application time, *atime* attribute is used for uniquely identify an application. The database keep tracks of the application time and whether it is approved or not by a Manager.
5. **Customer:** A Customer is a sub-entity of the Person entity, who is looking for a date with a Product on our platform. The database keeps track of the activity preferences of a Customer.
6. **Booking:** A booking is produced whenever a Booking Request is approved by a Product. It is uniquely identified by an artificial bookingId.
7. **Booking Status:** Booking status enumerates all the possible statuses of a Booking. A booking status entity is identified by its unique statusId, and it contains a description for the stus. A booking can have the following statuses: active, if the booking request was approved and the respective invoice has been paid; pending, if the booking has been placed but the invoice has not yet been paid, completed if the booking has been completed (i.e. the Customer and the Product finished the date successfully); and cancelled, if the customer decided to change his/her mind and not go the date anymore.
8. **Activity:** Activity enumerates all the possible activities that could possibly happen in a date. An activity can be of different types: movie at the cinema, strolling at the park, meal at restaurant, assistance to an event, etc. Each of this corresponds to an activity id. The id is the primary key.

9. **Invoice:** An Invoice consists of a description of the payment (i.e. the service), the charged amount and the due date. It is uniquely identified by an invoice id (artificial primary key).

1.2.2 Relationships

1. **Reviews:** A *manager* **reviews** an *application* send by a user for becoming a product. It is a one-to-many relationship, because a manager can review many applications. A key constraint is added to the application side, since an application can only be reviewed by one manager. Based on the information provided in the application, that manager shall decide whether to accept or reject the application. The database keeps track of the review time, decision made as well as a comment to the review.
2. **Applies:** A *product* **applies** an *application*. It is a one-to-many relationship with participation constraints. A product must send at least one application when he/she registers, and he/she is allowed to multiple applications if previous ones are rejected. An application must relate to one and at most one product.
3. **Rates:** A *Customer* **rates** a *product* on a *booking*. A customer can only rates a finished booking. This ternary relationship has a key constraint on booking since one booking can only be rated once. The database keeps track of rating date, rating number (1-5) and a comment.
4. **Pays:** A *Customer* **pays** an *invoice*; he does this with a certain amount of money, with a certain paying method (for simplification, mastercard, paypal, or visa).
5. **has:** A *booking request* **has** a *booking status*, which may belong to different types (see entities).
6. **Requests:** A *Customer* **requests** a *Product*, therefore producing a booking (whose status might or not be accepted.). The request time is recorded.
7. **Confirms:** Once a booking is made, a *Product* **confirms** the *Booking* (or rejects it).
8. **Involves:** A *booking* **involves** *activities*. There is a participation constraint at booking side because one booking must involve at least one activity.
9. **Contains:** A *booking* may **contain** an *invoice*. It is an one-to-one relationship with key and participation constraint. An invoice must belong to one and only one booking. A booking can have most one invoice for a confirmed booking, or not have an invoice for pending, rejected and cancelled bookings.

1.3 Comments

- A *Customer* can only leave a rating (**rates**) of a *Product* if the *Booking Status* is complete. This should be captured at the software level.

1.4 Application Description

1.4.1 Overview

The web-based application will all entities involved in the relational model to perform all described relations through an interactive interface. In particular, it will allow **customers** to book **Mates** by first seeing their pictures and descriptions of the products, and perhaps even filtering them, and then clicking a "boook me!" button. From there, the booking process takes place.

The diagram is a complex ER model with the following components:

- Entities and Attributes:**
 - User:** username, firstName, lastName, email, sex, city, phoneNumber, password, dateOfBirth.
 - Manager:** (No attributes shown).
 - Application:** appId, aTime, isApproved.
 - Mate:** nickname, description, language, height, weight, hourlyRate, preferences.
 - Customer:** preferences.
 - Request:** rinfo, rid, rstatus.
 - Order:** oid, startime, endime, ordStatus.
 - Invoice:** ind, description, amount, dueDate.
 - Activity:** aid, description.
- Relationships and Cardinalities:**
 - Applies:** Connects Application and Mate. Cardinalities: 1:M (Application to Mate), 1:M (Mate to Application).
 - reviews:** Connects Manager and Application. Cardinalities: 1:M (Manager to Application), 1:M (Application to Manager).
 - decide:** Connects Mate and Request. Cardinalities: 1:M (Mate to Request), 1:M (Request to Mate).
 - generate:** Connects Request and Order. Cardinalities: 1:M (Request to Order), 1:M (Order to Request).
 - contains:** Connects Customer and Order. Cardinalities: 1:M (Customer to Order), 1:M (Order to Customer).
 - schedule:** Connects Manager and Order. Cardinalities: 1:M (Manager to Order), 1:M (Order to Manager).
 - pay:** Connects Customer and Invoice. Cardinalities: 1:M (Customer to Invoice), 1:M (Invoice to Customer).
- Other Features:**
 - ISA:** A relationship between User and Mate, indicating inheritance.
 - modify:** A relationship between Manager and Order.
 - overview:** A relationship between Manager and Activity.
 - rates:** A relationship between Order and Invoice, with attributes: rating, comment, ratingDate.

Figure 1: ER Schema

3 ER Translation

- User(username, email, sex, city, phoneNum, password, dateOfBirth, firstName, lastName)
"username foreign key references User"
- Mate(username, nickName, description, language, height, weight, hourlyRate, preferences)
"username foreign key references User"
- Customer(username, preferences)
"username foreign key references User"
- Manager(username)
"username foreign key references User"
- Application(appid, username, aTime, isApproved, mngName, rTime, comment, decision)
"username foreign key references Mate"
"mngName foreign key references Manager"
- Request(rid, rinfo, rstatus, mateName, decTime)
"mateName foreign key references Mate"
- Order(oid, endTime, startTime, ordStatus, rid, inid, custName, ratingDate, comment, rating)
"rid foreign key references Request"
"inid foreign key references Invoice"
"custName foreign key references Customer"
- Invoice(inid, description, dueDate, amount, custName, pamount, paytime, method, status)
"oid foreign key references Order" "custName foreign key references Customer"
- Activity(aid, oid, description, mngName)
"oid foreign key references Order" "mngName foreign key references Manager"
- Start(rid, mateName, custName, startTime)
"mateName foreign key references Mate"
"custName foreign key references Customer"
- Modify(mngName, oid, modTime)
"mngName foreign key references Manager"
"oid foreign key references Order"
